

Supplementary Methods

Metagenome assembly methods

Details of genomic DNA sequence libraries are provided in **Supplementary Table S1**. Sanger end sequencing yielded average read lengths of 800 nucleotides. One 0.1 µm filter library was also pyrosequenced using 454 Titanium chemistry, with an average read length of 400 nucleotides. Assembly software parameters were systematically varied in preliminary assemblies to empirically identify settings producing maximum scaffold length, minimum gap length, and sharpest peak resolution in a length-weighted histogram of scaffold percent GC. Final assembly parameters were:

```
utgErrorRate=0.10
ovlErrorRate=0.10
cnsErrorRate=0.10
cgwErrorRate=0.12
utgBubblePopping=0
utgGenomeSize=500000
merSize=15
doFragmentCorrection=0
doExtendClearRanges=1
doResolveSurrogates=1
Unitigger parameter -j = -20.
```

Composite assemblies including all available libraries were used to classify scaffolds into one of four categories: Nanohaloarchaea, non-Nanohaloarchaea, ambiguous, or unclassified. Scaffold classifications were based on manual assessment of multiple independent parameters. Matches to known microbial 16S rRNA sequences were identified by BLASTN search against the GreenGenes reference database (DeSantis *et al.*, 2006), requiring a minimum alignment length of 200 nucleotides and e-value of 1e-7 or better. For each scaffold, number and alignment quality of predicted protein matches to GenBank sequences associated with previously sequenced halophilic archaeal genomes were assessed based on a BLASTX search against the GenBank nr database with an e-value cutoff of 1e-5 or better. For scaffolds longer than 3,000 nucleotides, distribution of reads derived from the 0.1 µm and 0.8 µm filter libraries and percent G+C nucleotide composition were also considered in determining scaffold origin.

A second, iterative round of assembly was performed combining all reads previously associated with scaffolds identified as possible Nanohaloarchaea, ambiguous or unclassified. Unassembled singletons reads were also included in the second round, but reads associated with scaffolds identified as non-Nanohaloarchaea were excluded. Scaffolds from the second round of assembly were classified according to the same procedures as the first round.

Phylogenetic analysis methods

Sixty-six individual ribosomal protein datasets from Euryarchaeotal genomes (**Supplementary Table S8**), including J07AB43 and J07ABA56, were aligned using MAFFT version 6.833 (Philippe, 1993). All alignments were visually inspected and manually corrected when necessary. Regions where the alignment was doubtful were removed prior to further phylogenetic analyses. Datasets for nine ribosomal proteins were discarded because of insufficient taxonomic sampling (L13e, L14e, L20a, L30e, L34e, L35ae, S25e, S26e, S30e), since these proteins were absent in more than 10 euryarchaeal genomes. The remaining 57 ribosomal proteins were combined to construct a single alignment containing 5858 amino acid positions. This alignment was subsequently recoded using Dayhoff 4 categories (ASTGP, DNEQ, RHK and MVILFWY, with cysteines being considered as missing characters) (Hrdy *et al.*, 2004; Susko and Roger, 2007). A subset of 43 of the original 68 archaeal genomes were selected to represent the diversity of Euryarchaeota, eliminating multiple closely related representatives of the same order (e.g. *Pyrococcus*, *Thermococcus*, *Methanosarcina*, and *Methanococcus maripaludis*).

Maximum likelihood (ML) phylogenetic analyses were performed using both TreeFinder v.10.08 (Jobb *et al.*, 2004) and PhyML version 3.0 (Guindon and Gascuel, 2003). The evolutionary model was chosen in agreement with the ‘propose model’ tool implemented in TreeFinder (AICc criterion). For the euryarchaeal 16S rRNA and the ribosomal protein recoded alignment analyses we used the General Time Reversible model, with empirical nucleic acids estimated frequencies, a gamma correction (4 discrete categories and an estimated alpha-parameter) to take into account evolutionary rate variation across sites. For the euryarchaeal 16S rRNA analysis we have also considered that a proportion of the sites were invariant (this proportion was estimated by ML). For the alignment of the non-recoded ribosomal protein concatenation analysis, the Le and Gascuel model with empirical amino acid estimated frequencies, a gamma correction (4 discrete categories and an estimated alpha-parameter), and an estimated frequency of invariant sites was employed. Additional ML phylogenetic analyses of these three datasets were performed using

PhyML with the same parameters. Finally, nanohaloarchaeal diversity (Figure 6) was inferred by ML phylogenetic analysis via TreeFinder using the J1 model and gamma correction. The robustness of each resulting ML phylogenetic tree was estimated using non parametric bootstrap approaches implemented in TreeFinder and PhyML (100 replicates of the original dataset).

Supplementary Table S1. Summary of Lake Tyrrell metagenomic sequencing libraries used in this study. Average read length is shown \pm standard deviation.

Library name	Retention Filter	Collection Date	Library type	Sequencing platform	Number of reads	Avg. read length
ABM	0.8 μ m	1/23/2007	8-10 kb plasmid	Sanger	81,197	776 \pm 157

Supplementary Figure Legends

Supplementary Figure S1. Location of sampling sites and sample characteristics.

Supplementary Figure S2. Unrooted maximum-likelihood phylogenetic trees for the Euryarchaeota. Trees are based on (A) 16S rRNA sequences (48 sequences, 1275 positions; NCBI accession numbers and coordinates provided in Supplementary Table S9) and (B) concatenation of 57 ribosomal proteins (43 sequences, 5858 positions). Names of euryarchaeal sub-lineages are shown in the box. Numbers at nodes represent bootstrap values (A) inferred by TreeFinder/PhyML; (B) inferred by TreeFinder based on amino acid alignments and the 4 state recoded amino acid alignments, shown in parentheses. Bootstrap values of less than 50% are indicated by "-" sign. Scale bar represents an average of 0.1 substitutions per site.
